08

Development and validation of gaming & simulation platforms that induce, measure and feedback stress to enhance the capability of the military to perform better under stressful circumstances

# RESEARCH PROJECT

# RESILIENCE MODEL

Cadets of Royal Dutch  
Military Academy  $N = 65$ ;

Military Resilience Monitor  
14 day's prior VR experiment

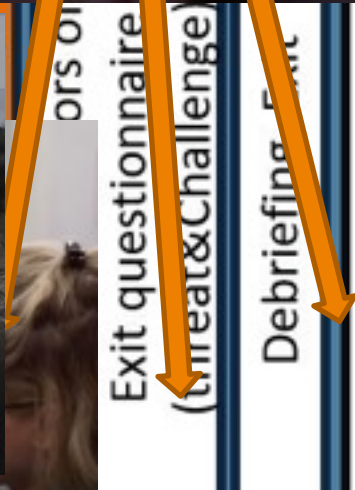

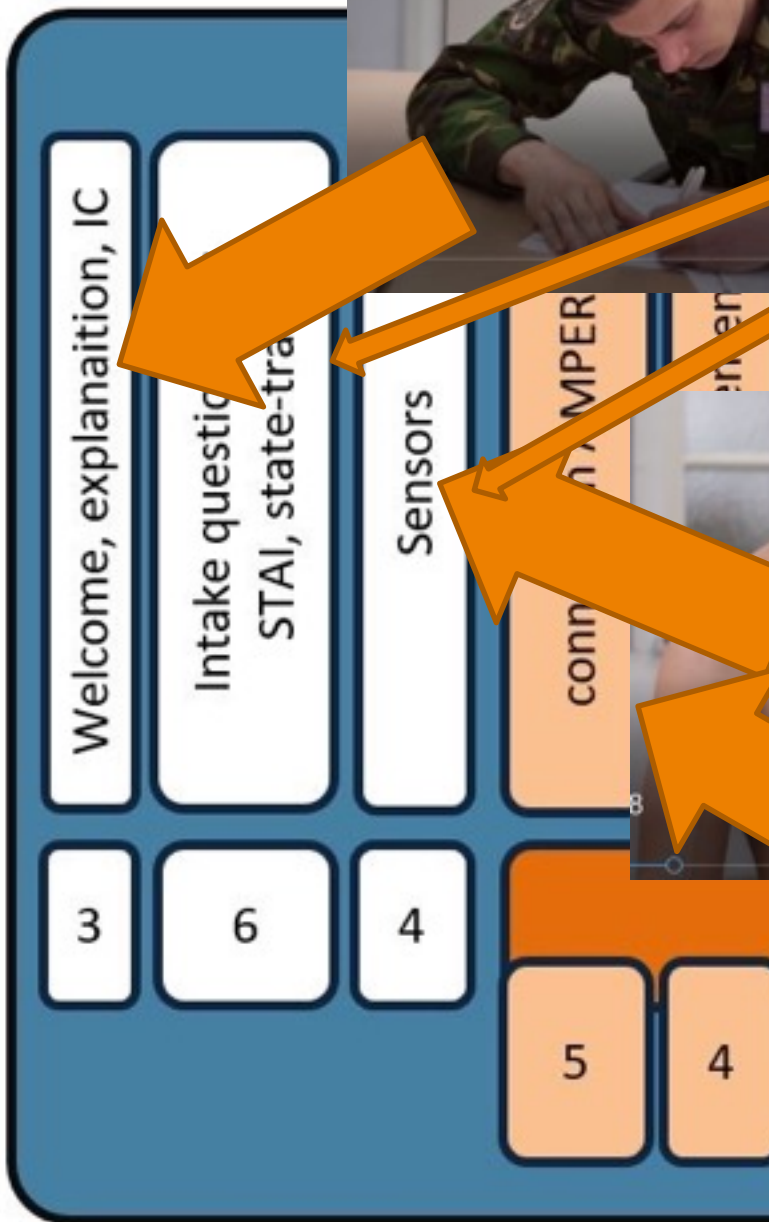

# E.G. IED SCENARIO

# TIMELINE

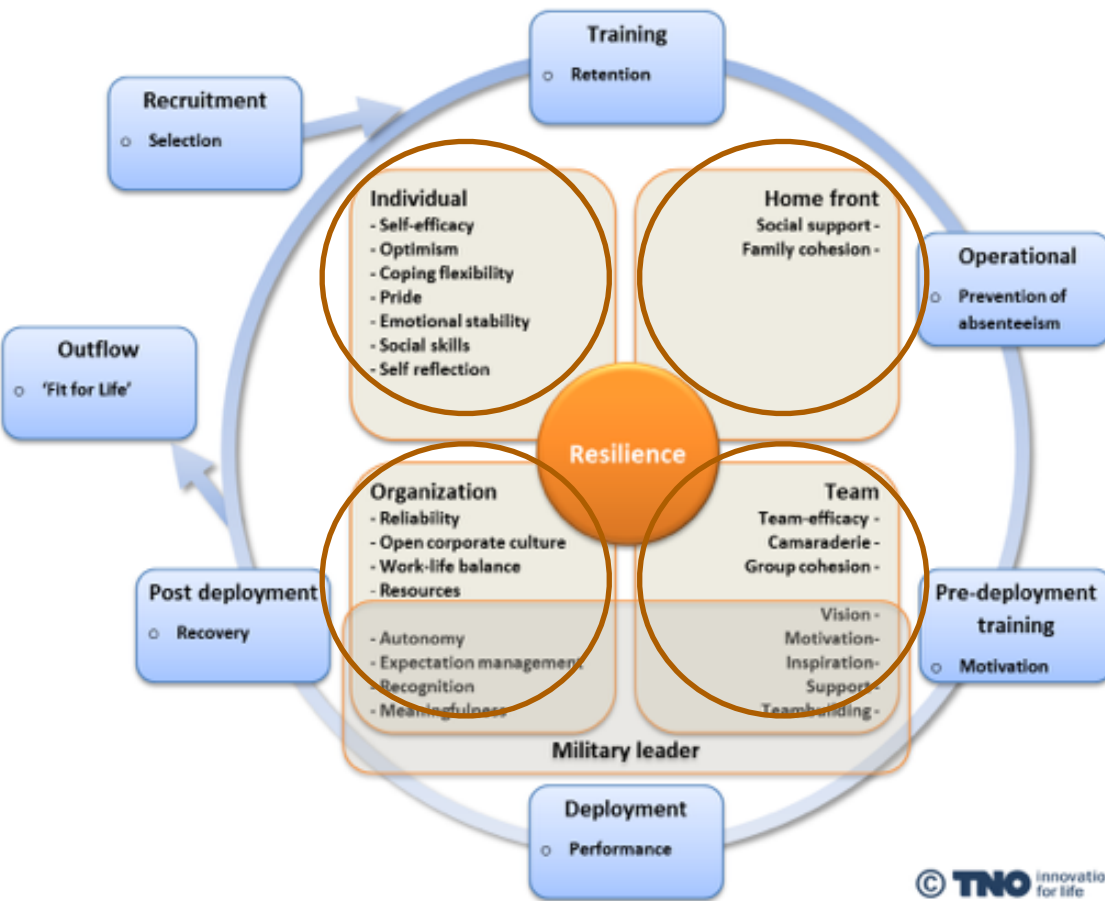

- › Physiology
  - › **Heart Rate (HR)**
    - › Heart Rate Variability (HRV)
  - › Blood Pressure (BP)
    - › Systolic (SBP)
    - › Diastolic (DBP)
  - › **Cardiac Output (CO)**
    - › Volume of blood pumped per minute
  - › Total Peripheral Resistance
    - › force required to maintain blood flow
  - › Galvanic Skin Response
    - › Average per phase
    - › Number of peaks
  - › **Salivary Cortisol**  
(engagement vs stress; cotton swaps)
- › Questionnaires
  - › STAI trait & state
    - › pre
  - › Threat & Challenge
    - › pre & post
  - › Dutch Military Resilience Monitor
    - › 14 days before the experiment
  - › Cognitive Performance Measure
  - › Situational Awareness Score

# MRM

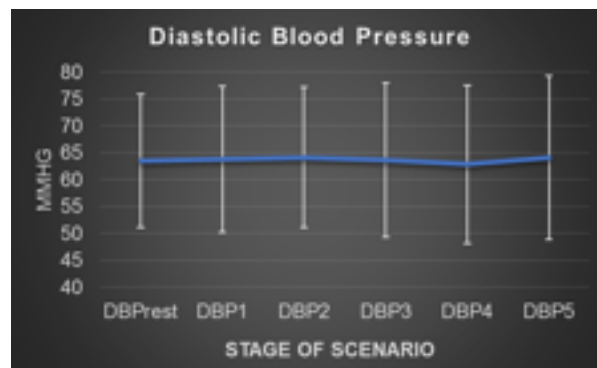

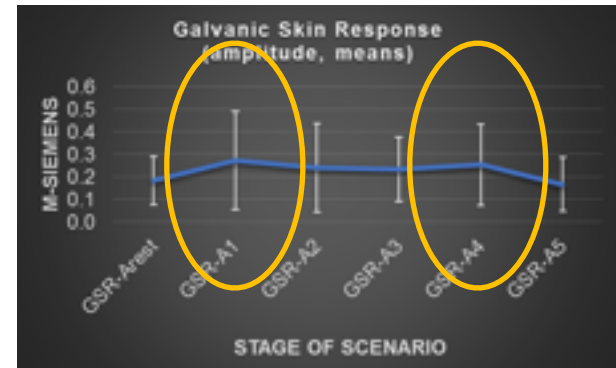

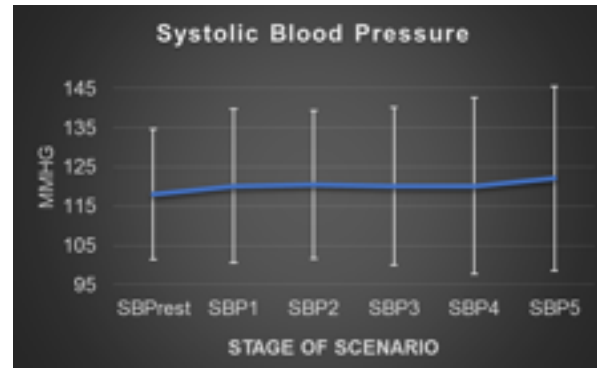

› Military Resilience Monitor: measures individual, homefront, team and organisational resources in short (30 items) scale. Validated for deployment phase.

- › Adapted for training setting:
  - › Emotional stability, self-efficacy, social competence
  - › Coping style (active, avoidance, social support, humor, acceptance, spiritual, reappraisal)
  - › Family support & cohesion
  - › Instructor support
  - › Group/team cohesion
  - › Reliability & open/safe culture

# PHYSIOLOGICAL RESULTS (GROUP)

# INDIVIDUAL RESULTS

- › We categorised the physiological responses in threat and challenge by applying the biopsychosocial model of stress (Blascovich and Mendes, 2000).
  - › Higher HR, higher CO, no increase of TPR → challenge state (+ stress)
  - › Higher HR, higher CO, increase of TPR → threat state (- stress)
    - › 29 participants showed challenge states
    - › 3 participants showed threat states
    - › (33 participants showed higher HR during the rest measurement in the run-up of the experiment compared to the first simulation scenario)
- › We used the threat and challenge survey (Drach-Zahavy & Erez, 2002) to examine whether the physiological classification in challenge and threat responders was in line with the individually perceived (psychologica) stress appraisals.

## MRM RESULTS (GROUP)

- Instructor support → higher cortisol level ( $r^2 = .42$ ;  $p < 0.01$ )
  - implying that if the cadets receive more instructor support, that lead to higher (physically) responses of engagement/activation (in the run-up of the experiment)
- Coping style 'avoidance' → higher cortisol level ( $r^2 = - .30$ ;  $p < 0.05$ )
  - implying that the applied coping style avoidance would lead to lower (physically) engagement/activation
- Coping style 'active' → higher cortisol level ( $r^2 = .31$ ;  $p < 0.05$ )
  - implying that the 'active' coping style lead to higher (physically) engagement/activation
- Coping style 'acceptance' → peripheral resistance ( $r^2 = .27$ ;  $p < 0.05$ )
  - implying that the emotion regulation to accept a challenging/threatening context lead to higher (threat) stress response.
- Coping style 'humor' → peripheral resistance ( $r^2 = - .29$ ;  $p < 0.05$ )
  - implying that the emotion regulation to engage a challenging/threatening context with 'humor' lead to lower (threat) stress responses during the simulated scenario's.
- Coping style 'humor' → higher heart rate and cardiac output  
 ( $r^2 = .32$ ;  $p < 0.02$ ;  $r^2 = .33$ ;  $p < 0.01$ , respectively)
  - implying that the trait/state of using humor in difficult situation leads to higher heart rate and blood flow during the simulated scenario's.

## RELATIONSHIP WITH EARLIER FINDINGS

- › In 2016, we found that cortisol and optimism were predictors of attrition/perseverance in a maritime infantry (Marines) training setting.
  - › Higher levels of cortisol were correlated with higher optimism scores (i.e., training success)
  - › The relationship between optimism and training perseverance were moderated by higher levels of cortisol.

Binsch, O., Van Wietmarschen, H., & Buick, F. (2016). Relationships Between Cortisol, Optimism, and Perseverance Measured in Two Military Settings. *Military Psychology*. <http://dx.doi.org/10.1037/mil0000146>.

# CONCLUSIONS

- It is possible to induce and measure arousal and indices of stress within VR gaming & simulation settings, also in the military domain.
- Different stressors are induced, also stressors only indirectly attributable to the VR&M gaming/simulation platform. VR necessary?
- Applying 'fancy' VR technology and add-ons are not a guaranty to induce more arousal and/or stress.
- Not every cadet was susceptible/sensible to VR settings and the simulated (military) VR scenario.
- Cortisol seems to be a reliable biomarker in predicting states of activation in young military service members.
- Relationship with cortisol implies that if the cadets receive more instructor support that lead to higher physical activation, higher chance of perseverance and training success.
