# Chloride interference during DOC analyses using wet chemical oxidation methods

André van Zomeren, Remco Koper, Joris J. Dijkstra  
and Rob N.J. Comans

IHSS conference, Ioannina  
September 5, 2014

# Energy research Centre of the Netherlands

---

# Background: Environmental impact assessment

- Environmental limit values for emissions to soil and groundwater
- → Dutch Soil Quality Decree (2007)
- **Validate assumptions on HA/FA concentrations in modelling**
- Rapid batch method available: consistent with IHSS methods, suitable for both solid and aqueous samples
- Change DOC analyses from “combustion method” to “chemical oxidation method”

# Rapid batch method

- Humic acids (HA)  
(precipitate at pH =1)
- Fulvic acids (FA)  
(bind to XAD8, desorbed with NaOH)
- Hydrophobic neutrals (HON)  
(bind to XAD8, not desorbed with NaOH)
- Hydrophylic acids (Hy)
- 1-2 hours per sample

# Standardisation of rapid batch procedure: ISO 12782-4 and -5

Secretariat: DIN

**Soil quality — Parameters for geochemical modelling of leaching and speciation of constituents in soils and materials — Part 5: Extraction of humic substances from aqueous samples**

*Qualité du sol — Paramètres pour la modélisation géochimique du lessivage et spécifications des constituants des sols et des matières — Partie 5: Extraction des substances humiques des échantillons aqueux*

# Methods: Shimadzu TOC Vcph

---

- TIC: acidification ( $\text{H}_3\text{PO}_4$ ) and detection of  $\text{CO}_2$
- TC: catalytic combustion at 680 C
- $\text{DOC} = \text{TC} - \text{TIC}$
- Combustion of DOC:  $\text{CO}_2$  and detection by NDIR
- $\text{DTL} \pm 1 \text{ ppm}$
- ISO 17025 accredited

# Methods: Sievers TOC 900

---

- TIC: acidification ( $\text{H}_3\text{PO}_4$ ) and detection of  $\text{CO}_2$
- TC: **wet chemical oxidation** with persulfate and UV
- $\text{DOC} = \text{TC} - \text{TIC}$
- Radical formation by persulfate and UV light
- Oxidation of DOC:  $\text{CO}_2$  and detection by conductometry
- **$\text{DTL} \pm 0.1 \text{ ppb}$**

# Comparison of analytical methods

---

# Fractionation in soil sample extracts

- Method: Sievers WCO

# Oxidation efficiency HS as a function of chloride concentration

- Dissolution of 5 mg C/L HS and addition of increasing NaCl to each bottle

# Oxidation efficiency HS as a function of chloride concentration

- Distinct differences between aquatic and soil HS
- Soil HS more easily oxidised than aquatic HS
- In soil FA is more easily oxidised than HA
- In Aquatic sample, HA is more easily oxidised than FA

# Oxidation efficiency as a function of chloride concentration

- Insensitive to chloride concentration
- Increase of oxalic acid to >100%?

# Oxidation efficiency as a function of chloride concentration

- Decrease in oxidation efficiency at relatively high chloride concentrations

# Oxidation efficiency as a function of chloride concentration

# Oxidation efficiency as a function of chloride concentration

# Oxidation efficiency as a function of chloride concentration

# Oxidation efficiency as a function of chloride concentration

- Acetic acid has lowest recovery
- Oxalic and malonic acid relatively high recovery
- Increase of oxalic acid to >100%?
- Why different recovery for each substance?
- Overall, HS seem to be more easily oxidised than small organic acids

# Oxidation efficiency as a function of pKa1

# Oxidation efficiency as a function of pKa1

- Stronger acids are more easily oxidised
- Since pKa reflects part of the chemical structure, this is probably important to explain results
- No indication of exact mechanism

# Conclusions

---

- Use of standardised methods important for research and geochemical modeling tools
- HS concentrations at low levels are challenging to analyse
- Chloride interference substantial for both organic acids and HS
- pKa seems to have relation with oxidation efficiency
- Exact mechanisms remain unknown but type of organic carbon is important
- Measurement of chloride concentrations is important when using WCO

# Thanks for your attention!

---

soil

protection level at "point  
of compliance" (POC)

# Rationale for a rapid procedure for NOM fractionation

- 
- Classical isolation and purification procedures (IHSS) are very elaborate:
  - Throughput time for samples is typically 2-4 weeks
  - Labour time is approximately 20-40 hours/sample
  - Not suitable for routine analysis
  - → Development of insight in the concentrations of sub-fractions of NOM in soils and natural waters and their role in ecosystem services such as soil carbon storage, food production and quality of groundwater
  - → Rapid batch method, consistent with IHSS methods, suitable for both solid and aqueous samples

# Background

---

- Involved in deriving environmental limit values for emission of dangerous substances from construction products
- Long-term scenario modelling using state of the art approach:
  - Geochemical speciation modelling
  - Adsorption to iron-oxides
  - Complexation with humic substances
- Indications that the assumed HS concentration in soil pore water and ground water was too low
- Possible implication: under estimation of predicted emissions and emission limits should be more strict
- Need for analytical methods to determine HS at low concentrations
