Abstract Characterization of humic substances (HS) in environmental samples generally involves labor-intensive and time-consuming isolation and purification procedures. In this paper, the development of an automated system for HS isolation and purification is described. The novelty of the developed system lies in the way the multiple liquids and columns used in the isolation/purification procedure are handled in both forward and back-elution mode by solenoid valves. The automated procedure significantly reduces the total throughput time needed, from 6–7 days to 48 h, and the amount of labor to obtain purified HS for further characterization. Chemical characterization of purified HS showed that results were in good agreement with previously published values for HS from a variety of sources, including the IHSS standard HS collection. It was also shown that the general properties of HS were consistent among the different source materials (soil, waste, aquatic) used in this study. The developed system greatly facilitates isolation and characterization of HS and reduces the risk of potential

(time-dependent) alteration of HS properties in the manual procedure.

Keywords Natural organic matter · Humic acid · Fulvic acid · Isolation · Purification · IHSS method

Introduction

Natural organic matter (NOM) in the environment can be of plant, animal, or microbial origin and may range from relatively fresh to highly decomposed and transformed. NOM plays an important role in, for example, soil properties such as cation-exchange capacity, soil structure, water entry and retention, nutrient cycling, and binding of heavy metals and organic micropollutants [1, 2]. The study of these properties often requires isolation and purification of organic matter.

Currently, the International Humic Substances Society (IHSS) uses the adapted fractionation method of Aiken [3], earlier described in detail by Thurman and Malcolm [4], for isolation and purification of humic (HA) and fulvic acid (FA) standards from aqueous samples, and the method of Swift [2] for solid source materials. These methods are based on precipitation of HA at pH 1 or 2 and adsorption of HA and/or FA on the macroporous XAD-8 resin. Adsorbed HS are subsequently desorbed with 0.1 mol L⁻¹ NaOH and cations are removed by a cation-exchange resin. The reader is referred to Refs. [2–5] for detailed descriptions of the methods of isolation. Although these procedures are well established and widely used by scientists, they all share the disadvantage of being very laborious, particularly because of the manual handling of the multiple liquids and columns that are required.

This paper describes the development of an automated system to perform isolation and purification of HS, especially from solid source materials. The setup of the system is very flexible and easy to modify, which allows methods that involve HA separation after prior preconcentration and purification (e.g. Thurman and Malcolm [4] and Leenheer [5]). However, these methods then involve intermediate HA separation by acidification and centrifugation. The novelty of the method lies in the automated handling of the multiple liquids and columns, required in the isolation/purification procedure, in both forward and back-elution mode. The particular experimental set up allows the procedure to be executed with only a single pump and flowmeter. Our main objective for automation of the IHSS procedure was to save a significant amount of labor and total throughput time in the performance of HS isolation and purification. By automating the procedure, our objective is also better standardization of the HS isolation and purification methods.

Materials and methods

Reagents

All reagents used were of analytical-grade quality. Double demineralized water (nanopure) was used for preparation of reagents. Every new batch of XAD-8 (Amberlite) was

first cleaned to remove organic impurities by five consecutive 24-h extractions with 0.1 mol L^{-1} HCl and 0.1 mol L^{-1} NaOH. Fine floating particles were removed by decantation. The XAD-8 and the cation-exchange resin (Biorad AG-MP-50, 100-200 mesh) resin were thoroughly cleaned by Soxhlet extraction with acetonitrile and methanol, each for 24 h. The cleaned resins were stored in methanol until use.

Samples

The automated procedure was performed (according to Swift [2]) on a peat (Devoke UK), a compost sample, a landfill waste mixture, and a sample of municipal solid waste incineration (MSWI) bottom ash. Moreover, HS from four aquatic samples, a landfill leachate, influent and effluent water from a landfill water treatment plant, and water from a DOC-rich pond in a nature reserve (Zwanenwater, NL), were isolated and purified according to Thurman and Malcolm [4]. All purified HS (except from MSWI bottom ash) were also characterized by the method of van Zomeren and Comans [6].

Hardware

The experimental setup of the procedure is outlined in Fig. 1. The lines in the scheme represent Teflon tubing (FEP, 1/8" O.D., 1/16" I.D.) connected to several two-way

Fig. 1 Schematic representation of the automated isolation and purification system. An asterisk marks the manual option (Omnifit manual three-way connector, part: 1102) to de-aerate the tubing and the pump before each experiment. Dashed lines mark connections from fractions that are first produced (F2 and F4) in the procedure and that are later used in subsequent elution steps (FA1 + FA2 and FA3). N_2 gas was supplied to the eluate FA3 (fraction 4) until it was purified by the cation-exchange resin. Sample vessels F2 (containing 6 mol L^{-1} HCl and concentrated HF) and F4 were placed on a magnetic stirrer with a Teflon-coated magnet to homogenize the solution

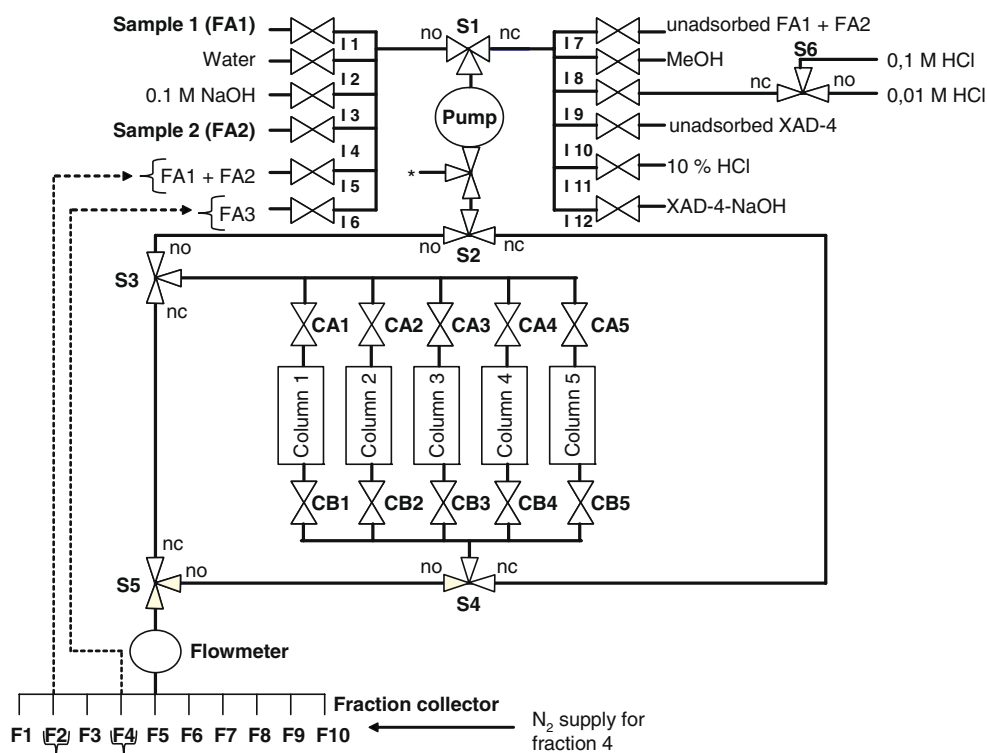

Table 1 Procedure statements used to perform the isolation and purification procedure of Swift [2]

Step	Description	Stop volume	Column	Fraction	Flow	Deviation
1	Pumping water through column 4 (i2)	20×cv4	4	3	fl4	5
2	Pumping 10% HCl through column 4 (i11)	15×cv4	4	3	0.6×fl4	5
3	Pumping water through column 1 (i2)	20×cv1	1	3	fl1	5

6	Pumping 0.01 mol L ⁻¹ HCl through column 1 (i8)	1.5×cv1	1	3	fl1	5
7	Pumping FA1 through column 1 (i1)	0.95×FA1	1	1	fl1	5
8	Pumping 0.65 column volumes of water through column 1 (i2)	0.65×cv1	1	1	fl1	5
9	Back-eluting with 1.5 column volume of 0.1 mol L ⁻¹ NaOH (i3)	1.5×cv1	1	2	fl1	5
10	Back-eluting with 3.5 column volumes of water (i2)	3.5×cv1	1	2	fl1	5
11	Pumping 0.01 mol L ⁻¹ HCl through column 2 (i8)	1.5×cv2	2	3	fl2	5
12	Pumping FA2 through column 2 (i4)	0.98×FA2	2	6	fl2	5
13	Pumping 0.65 column volumes of water through column 2 (i2)	0.65×cv2	2	6	fl2	5
14	Back-eluting with 1.5 column volumes 0.1 mol L ⁻¹ NaOH (i3)	1.5×cv2	2	2	fl2	5
15	Back-eluting with 3.5 column volumes of water (i2)	3.5×cv2	2	2	fl2	5
16	Pumping 0.01 mol L ⁻¹ HCl through column 3 (i8)	1.5×cv3	3	3	fl3	5
17	Pumping FA1+FA2 through column 3 (i5)	4.9×(cv1+cv2)	3	1	fl3	5
18	Pumping 0.65 column volumes of water through column 3 (i2)	0.65×cv3	3	1	fl3	5
19	Back-eluting with 1.5 column volumes 0.1 mol L ⁻¹ NaOH (i3)	1.5×cv3	3	4	fl3	5
20	Back-eluting with 3.5 column volumes of water (i2)	3.5×cv3	3	4	fl3	5
21	Pumping water through column 4 (i2)	20×cv4	4	3	fl4	5
22	Pumping FA3 through column 4 (i6)	4.9×(cv3)	4	5	fl4	5
23	Pumping 2 column volumes of water through column 4 (i2)	2×cv4	4	5	fl4	5

The steps are executed in increasing number until the stop volume is reached. Sample (FA1/FA2) and column volumes (CV<n>) are entered by the user in the user interface and the flow (FL<n>) is derived from these volumes (default: 5 CV h⁻¹). Column number, fraction number, and the deviation in the stop volume (%) are given for each step

(Takasago, type, 24 V DC) and three-way solenoid valves (Furon, model 1101493, 24 V DC) by Omnifit PEEK fitting nuts (part 2222) and grippers (part 2312). All valves and fraction-collector positions of the system were named and

used in the database (see “Software” section) to specify their function (Tables 1 and 2). The position of the fraction collector is denoted F1-10 (Fraction). The two-way valves that control the liquid to be pumped are named I1-

The grey cells indicate that the appropriate valve is opened during the specific step in the procedure

12 (input). The system contains two blocks (Takasago, MTV-2-6NMFG-1, 24 V DC) with six solenoid valves (manifolds). Additionally, two manifolds (Takasago, MTV-2-5NMFG-1, 24 V DC) with five valves above and below the columns are named CA1-5 and CB1-5 (Column), respectively. The system was developed to perform the isolation and purification procedures of Swift [2], Thurman and Malcolm [4], and Leenheer [5]. Therefore, the connections and liquids for all of these methods are addressed in Fig. 1 (e.g. liquid inputs I8, I9, and I12).

The six three-way valves (S1-6, Switch) were used to reverse the flow to perform back elution during recovery of the purified HS. The normally open (no) and normally closed (nc) positions of the valves are noted in Fig. 1. Glass columns (Omnifit 2.5 cm I.D.×40 cm for XAD-8 and Omnifit 1.5 cm I.D.×40 cm for AG-MP-50) were used and the adjustable endpieces (2008NS and 6465NS) were equipped with 100 µm PTFE frits (6243NS).

All liquids were pumped (ProMinent Verder; Type: GALA1602TTT000UA002000) after the appropriate set of valves was opened (Tables 1 and 2). To reduce pressure pulses from the pump, either silicone tubing (0.7 mm I.D., 1 mm O.D.) or special crimped flexible PTFE tubing (3 mm I.D., 5.5 mm O.D., Polyflur, NL) can be installed behind the pump. The flow was measured with a liquid flowmeter (G.J.C. Instruments, model 5025500) and adjusted to the set point value by the software. A home-made rotating fraction collector collected the eluates in the various bottles using a stepper motor (Astrosyn, Y129, art. 586389, 12 V DC, 0.16 A). The home position (fraction number 1) was determined with an inductive sensor (Balluff, BES 516-3005-E4-C-PU-05).

Communications

The data I/O system contains several modules (Wago) for control of the valves, pump, inductive sensor, and stepper motor. All modules and their functions are specified in Table S1, the connections are shown in Figure S1 (Electronic Supplementary Material). The I/O modules were connected to the fieldbus network system (Modbus/RS232 communication) by a fieldbus controller (750-814), which was connected to COM1 of the PC. The second serial port of the PC (COM2) was used to communicate with the liquid flowmeter (RS232).

Software

The software was developed to control the pump, valves, flow meter, and fraction collector and includes a user interface to specify experiments. During the experiment the current status of each step is displayed and the user is allowed to stop or pause the experiment. Liquid volumes,

elapsed time, flow, and experiment set points are written to a data file. A Flow diagram showing the sequence of events during execution of a typical experiment is shown in Fig. 2. The software can be obtained from the authors free of charge.

The experimental configuration, procedure definitions (Table 1) and Modbus protocol register addresses (Table 2) were stored in a MS Access database.

Elemental analysis of purified HS

The elemental composition (CHNO) of the purified HS (after drying at 110 °C) was analyzed with a Carlo Erba

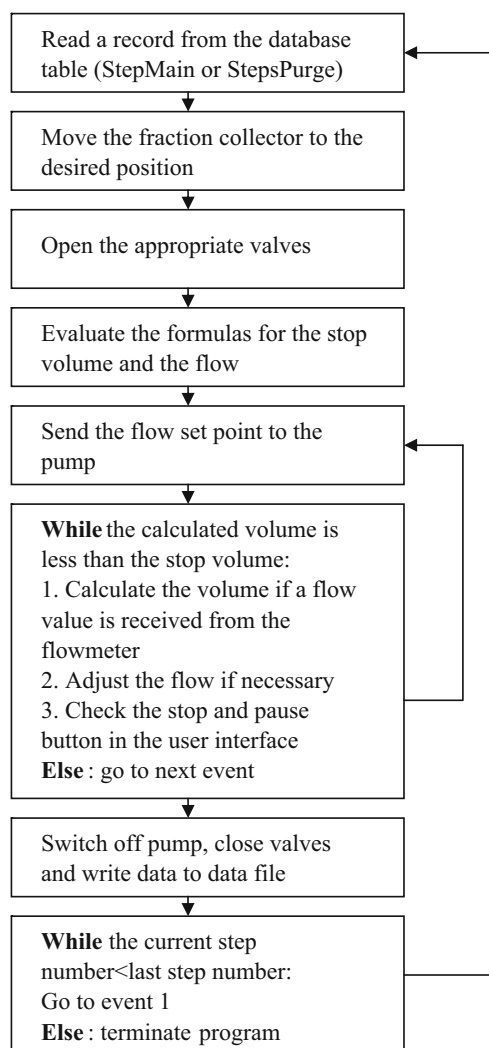

Fig. 2 Flow diagram showing the sequence of events during the execution of a typical experiment. The data used in the sequence are read from Table 1. The flow is adjusted by addition or subtraction of the offset in the flow (set point flow-actual flow). The experiment can be stopped or paused in the user interface at any time during the experiment

Table 3 Chemical composition (based on dry matter and ash free basis) in % (w/w) and UV–visible characteristics of isolated and purified HA and FA from various sources

^a Measured at 280 nm, based on the molar mass of carbon

^b Based on UV absorption at 280 nm, according to Ref. [10]

^c Atomic ratio

^d Relatively high ratio because of very low absorption at 665 nm

Flash EA 1112 element analyzer. Elemental S was determined by ICP-AES after digestion in HNO₃/HClO₄. The water content of the HS was determined separately on “as stored” samples by a Karl Fischer titration. The ash content was determined by subtraction of the total C, H, N, O, and S content from 100%.

Results and discussion

Performance characteristics of the automated procedure

The total throughput time of the automated system is about 48 h when a sample is isolated according to Swift [2]. Since the automated procedure also continues during the night, the purification process is finished after two working days. It is obvious that a significant additional amount of time is saved on checking/adjusting the experimental progress. It is noted that time saving only occurs in the column operation procedure itself, since the several sample extractions (acid and base) before the column procedure and the subsequent freeze drying of the obtained FA product are identical to the manual procedure.

Without the intention of specific comparison with the manual procedure, we tested the accuracy of the purified FA amounts in a duplicate isolation experiment with the compost sample. It was found that the differences were within 5% (3701 and 3586 mg FA kg⁻¹), suggesting an excellent experimental performance.

Results of the automated procedure are in good agreement with those obtained by use of a recently developed rapid batch procedure for quantification of HS [6]. The recovery of HA and FA was found to depend on the extraction conditions, in particular pH, HS concentration, and resin loading. Because these conditions do not differ between the manual and automated procedure, the HS recovery of both procedures will be identical.

Moreover, automation of the isolation procedure also overcomes practical problems in the planning of the experimental work. When the IHSS method [2] is performed manually, the total throughput time is about 6–7 days. Therefore, it is almost inevitable that the semi-purified HS are subjected to prolonged standing in acid or base. It has been found that FA storage in acidic solutions may induce polymerization, whereas storage in alkaline solutions can also lead to significant alteration of the

organic matter characteristics [7]. In addition, adsorbed HS might remain on the XAD-8 resin overnight before being desorbed. This is also unwanted because of resin bleeding [8, 9], that will be higher for increasing contact times. Therefore, we suggest that the original properties of FA are better retained by the new automated system.

Practical considerations

Before the experiment, air is manually removed from the tubing with a syringe (at point * in Fig. 1) and by bypassing the columns with a manually operated three-way valve. When running experiments at flow rates above about 10 mL min⁻¹, degassing the demineralized water in an ultrasonic water bath is recommended.

The first purified alkaline FA extract (steps 9, 10, 14 and 15 in Table 1) is immediately acidified with 6 mol L⁻¹ HCl (added manually to bottle F2 before start of the procedure) to prevent possible auto-oxidation of the alkaline FA extract. Concentrated HF can be used to reduce the ash content of the FA, yet there is still debate about its effects on the properties of purified FA [7]. To prevent possible damage of the flowmeter (which contains a glass measuring tube), concentrated HF is added by use of a home made semi-floating vessel which is designed such that the HF is added after about half of the total eluted volume has entered the collection bottle.

Chemical characterization of purified HS

Relevant properties of the samples that have been isolated and purified with the new automated procedure are summarized in Table 3. These results are generally in good agreement with other published values for HS from a variety of sources, including standard HS from the IHSS [10–12]. Given the heterogeneous nature of HS, we conclude that the automated procedure provides purified HS fractions that are comparable with those obtained with the manual procedure. In addition, the results in Table 3 show that the general properties of HA and FA are consistent among the different source materials (soil, waste, aquatic).

Conclusions

The presented automated system greatly facilitates isolation and characterization of HS. The system significantly reduces the total throughput time needed, from 6–7 days to 48 h, and the amount of labor required to obtain purified HS for further characterization. The properties of purified

HS obtained with the automated procedure are comparable with published values for HS from a variety of sources, including standard HS from the IHSS. Our results also show that the general properties of HA and FA are consistent among the different source materials (soil, waste, aquatic) used in this study. Automation of the isolation and purification procedure reduces the risk of alterations in HS properties resulting from potentially prolonged standing of HS in acid and/or base, or effects from resin bleeding. Therefore, it is concluded that the presented automated procedure enables better standardization of HS isolation and purification methods because of the standard operating protocol facilitated by the software.
